Arizona Border Region Influenza Report
MMWR Weeks 42-43 (October 12, 2014-October 25, 2014)

Border Influenza Activity Highlights:
- There were no confirmed cases of locally acquired influenza in Weeks 42 and 43 from the Arizona border region counties (Cochise, Pima, Santa Cruz, and Yuma).
- There were 3 cases enrolled in the Severe Acute Respiratory Infection (SARI) Surveillance in epidemiologic Weeks 42 and 43.
- Influenza-like illness activity at sentinel providers was below the baseline level in Week 42.
- The cases included in this report represent a small proportion of the true number of cases of influenza. Many people do not visit the doctor when ill and doctors should not be expected to run tests on all patients exhibiting influenza-like symptoms.
Influenza-Like Illness (ILI) Sentinel Provider Surveillance:

In Arizona’s border region 19 providers are enrolled in the national Outpatient Influenza-like Illness Surveillance Network (ILINet). The border region is defined as the geographical area approximately 100 kilometers (60 miles) north and south of the US/Mexico border. On a weekly basis, these sentinel sites report the total number of patients seen with Influenza-like Illness (ILI) and the total number of patients seen. ILI is defined as a fever of at least 100°F plus either a cough or a sore throat in absence of a known cause other than influenza.

Percentage of Visits for ILI at Sentinel Providers, Arizona-Border Region:

The proportion of patient visits to sentinel providers for ILI in the Arizona border region was 1.5% for week 42 (Week ending 10/18/14) which is below the baseline level for the border region. The border region ILI baseline is 1.55%*. The epidemic threshold for the Arizona border region is 2.52%*. In weeks when a relatively low number of reporting providers are present, the ILI proportion may not be representative for the border region of Arizona.

Laboratory-Confirmed Cases Reported, by County, 2014-2015 Influenza Season:

Two laboratory-confirmed cases of influenza were reported for Arizona during week 42 but both cases were not confirmed to be locally acquired. Therefore, no local transmission has been confirmed for the 2014-215 season.
The Arizona Border Infectious Disease Surveillance (BIDS) program of the Office of Border Health has initiated enhanced sentinel-site surveillance at selected acute care hospitals within the Arizona border region. The sites are not ILI-Net providers but provide additional information on influenza results* on a weekly basis.

**Severe Acute Respiratory Infections (SARI) Surveillance**

Severe Acute Respiratory Infections (SARI) surveillance is currently conducted by the BIDS program at selected hospitals in Arizona counties in the US-Mexico border region. SARI is defined as a hospital admission with onset within the last 10 days with a fever of at least 100.4°F (or a history of fever) plus a cough. Integrating hospital-based surveillance for SARI with existing influenza surveillance will complement and strengthen both of these surveillance activities. Enhancing hospital-based surveillance for respiratory pathogens will increase the ability to detect influenza strains currently in circulation, and monitor causes of morbidity and mortality among inpatients with SARI. Overall, this will provide a clearer epidemiological picture of influenza activity in our community.

SARI cases are tested by a reverse-transcriptase polymerase chain reaction (RT-PCR) viral panel test that includes: respiratory syncytial virus A and B; parainfluenza virus 1, 2, 3, and 4; human metapneumoviruses A/B; rhinovirus; adenovirus (B, C, and E); influenza A, A H1 (seasonal subtype), A H3 (seasonal subtype), A H1N1, and B; and coronavirus (NL63, HKU1, 229E, and OC43). After conducting further patient chart reviews, bacterial testing results performed on site have been found and incorporated into the graph below.

*Rather than performing rapid influenza diagnostic testing, BIDS site 4 utilizes a real-time RT-PCR assay which detects influenza A/B and respiratory syncytial virus (RSV) as their form of a rapid diagnostic test.
These cases are considered provisional until state-reviewed.

**Gender Distribution**

**Virologic Data**

One of the BIDS programs sentinel sites has been providing virologic data from all the molecular respiratory testing done in the hospital site. This graph found on the next page includes several reportable conditions such as influenza and respiratory syncytial virus (RSV), and also infections that are not reportable such as adenovirus, parainfluenza, coxsackievirus/echovirus, rhinovirus, and coronavirus. These aggregate data show trends in respiratory pathogens among all patients receiving the molecular testing.

**ACKNOWLEDGEMENTS:**

We gratefully acknowledge all our border partners for their contributions and support of the border influenza network including: Border Infectious Disease Surveillance Program, Early Warning Infectious Disease Surveillance, Naval Health Research Center Laboratory, Cochise County Health Department, Pima County Health Department, Santa Cruz County Health Department, Yuma County Health Department, and all participating hospital facilities.
